  "working_dir": "${file_path}",
  "selector": "source.c++, source.cpp",
}
```

## 2 Data Structures

### 2.1 Fenwick

```
/*All indices are 1 indexed*/
/*Range update and point query: maintain BIT of prefix sum of updates
to add val in range [a,b] add val at a and -val at b
value[a]=BITsum(a)+arr[a] where arr is constant*/
/**Range update and range query: maintain 2 BITs B1 and B2
**to add val in [a,b] add val at a and -val at b+1 in B1. Add val*(a-1) at a and -val*b at b+1
**sum[1,b]=B1sum(1,b)*b-B2sum(1,b)
**sum[a,b]=sum[1,b]-sum[1,a-1]*/
ll n;
ll fen[MAX_N];
void update(ll p,ll val){
    for(ll i = p;i <= n;i += i & -i)
        fen[i] += val;
}
ll sum(ll p){
    ll ans = 0;
    for(ll i = p;i;i -= i & -i)
        ans += fen[i];
    return ans;
}
```

### 2.2 2D-BIT

```
//point updates and range sum in a ractangle
//all indices are 1 indices. to increment value of cell (i,j) by val call update(x,y,val)
//to find sum of rectangle [a,b]-[c,d] find sum of rectangles [1,1]-[c,d],[1,1]-[c,b],
//[1,1][a,d] and [1,1]-[a,b] and use inclusion exclusion
ll bit[MAX][MAX];
```

```
void update(ll x , ll y, ll val)
{
    while( x < MAX )
    {
        ll y1 = y;
        while( y1 < MAX )
            bit[x][y1] += val , y1 += ( y1 & -y1 );
        x += ( x & -x );
    }
}
ll sum(ll x , ll y)
{
    ll ans = 0;
    while( x > 0 )
    {
        ll y1 = y;
        while( y1 > 0 )
            ans += bit[x][y1] , y1 -= ( y1 & -y1 );
        x -= ( x & -x );
    }
    return ans;
}
```

### 2.3 Segment Tree

```
/*
Sum segment tree
All arrays are 0 indexed. How to use:
to build segtree for arr[n] build(0,n-1,1)
to increment all values in [x,y] by val: upd(0,n-1,1,x,y,val)
call ppgt before every recursive call
to get sum of range [x,y]: sum(0,n-1,1,x,y)
for an array of size N use segment tree of size 4*N
*/
#define ll long long
const ll N=1e5+10;
ll arr[N],st[N<<2], lazy[N<<2];
void ppgt(ll l, ll r,ll id)
{
    if(l == r) return;
    ll m = l + r >> 1;
    lazy[id << 1] += lazy[id]; lazy[id << 1 | 1] += lazy[id];
    st[id << 1] += (m - l + 1) * lazy[id];
    st[id << 1 | 1] += (r - m) * lazy[id];
    lazy[id] = 0;
}
void build(ll l,ll r,ll id)
{
    if(l==r) { st[id] = arr[l]; return; }
    build ( l, l+r >>1 , id<< 1); build( (l + r >> 1) + 1, r , id<< 1 | 1);
    st[id] = st[ id << 1] + st[id << 1 | 1];
}
```

```

void upd(ll l,ll r,ll id,ll x,ll y,ll val)
{
    if (l > y || r < x ) return;
    ppgt(l, r, id);
    if (l >= x && r <= y ) { lazy[id] += val; st[id] += (r - l + 1)*val; return;}
    upd(l,l + r >> 1,id << 1, x, y, val);upd((l + r >> 1) + 1,r ,id << 1 | 1,x, y, val);
    st[id] = st[id << 1] + st[ id << 1 | 1];
}
ll sum(ll l,ll r,ll id,ll x,ll y)
{
    if (l > y || r < x ) return 0;
    ppgt(l, r, id);
    if (l >= x && r <= y ) return st[id];
    return sum(l, l + r >> 1,id << 1, x, y) + sum((l + r >> 1) + 1,r ,id << 1 | 1,x, y);
}

```

## 2.4 Persistent Segment Tree

```

/*Persistent Segment Tree for sum with point updates and range sum
Usage: See sample main for kth largest number in a range
**id of first node is 0. call build(0,n-1) first. afterwards call upd(0,n-1,previous id,i,val) to add val in ith number. it returns root of new segment tree after modification
**sum(0,n-1,id of root,l,r) gives sum of values in whose index is between l and r in tree rooted at id
**size of st,lchild and rchild should be at least N*2+Q*logN
*/
const ll N=1e5+10;

        --i;--j;
        ll ans=gkth(0,n-1,(i==0?-1:ids[i-1]),ids[j],k);
        cout<<v[ans].F<<endl;}
}

```

## 2.5 DP Optimization

```

/*You have an array of size L.You need to split it into G intervals, minimizing the cost. (G<=L otherwise we can just split in 1-intervals).
There is a cost function C[i,j] of taking an interval [i,j]. The cost function satisfies : C[a,b]+C[c,d]<=C[a,d]+ C[c,b] for all a<=b<=d.

```

This is the quadrangle inequality and intuitively you can think that the cost function increases at a rate which is more than linear at all intervals (may not be strictly true). So, if the cost function satisfies this inequality, the following property holds:

$F(g, l)$  : min cost of splitting first  $l$  elements into  $g$  intervals

Basic recurrence :  $F(g, l) = \min(F(g-1, k) + C(k+1, l))$  over all valid  $k$ .

$P(g, l)$  : lowest position  $k$  s.t. it minimizes  $F(g, l)$ .

$P(g, 0) \leq P(g, 1) \leq P(g, 2) \dots \leq P(g, l-1) \leq P(g, l)$ . ( $\leftarrow$  DivConqOpti,  $O(G.L.\log(L))$ )

Also,  $P(0, l) \leq P(1, l) \leq P(2, l) \dots \leq P(G-1, l) \leq P(G, l)$ .

This with previous inequality leads to Knuth Opti, complexity  $O(L.L)$ .

For div&conq, we calculate  $P(g, l)$  for each  $g$  1 by 1.

In each  $g$ , we calculate for mid-1 and solve recursively using the obtained upper and lower bounds. For knuth, we use  $P(g, l-1) \leq P(g, l) \leq P(g+1, l)$ , and fill our table in increasing  $l$  and decreasing  $g$ .

In opt. BST type problems, use  $bk[i][j-1] \leq bk[i][j] \leq bk[i+1][j]$ . \*/

// Code for Divide and Conquer Opti  $O(G.L.\log(L))$ : -

```

### 3.6 MCMF

```

// MCMF Theory:
// 1. If a network with negative costs had no
negative cycle it is possible to transform it into
one with nonnegative
costs. Using Cij_new(pi) = Cij_old + pi(i) -
pi(j), where pi(x) is shortest path from s to x in
network with an
added vertex s. The objective value remains
the same (z_new = z + constant). z(x) = sum(cij *
xij)
// (x->flow, c->cost, u->cap, r->residual cap).
// 2. Residual Network: cji = -cij, rij = uij - xij,
rji = xij.
// 3. Note: If edge (i,j),(j,i) both are there then
residual graph will have four edges b/w i,j (pairs
of parallel edges).
// 4. let x* be a feasible soln, its optimal iff
residual network Gx* contains no negative cost
cycle.
// 5. Cycle Cancelling algo => Complexity O(n*m^2*U*
C) (C->max abs value of cost, U->max cap) (m*U*C
iterations).
// 6. Successive shortest path algo => Complexity O(n
^3 * B) / O(nmBlogn)(using heap in Dijkstra)(B ->
largest supply node).
// Works for negative costs, but does not work for
negative cycles
// Complexity: O(min(E^2 * V log V, E log V * flow))
// to use -> graph G(n), G.add_edge(u,v,cap,cost), G.

## 6 Maths

### 6.1 Chinese Remainder Theorem

```

/*solves system of equations x=rem[i]%mods[i] for any ←
mod (need not be coprime)
input: vector of remainders and moduli

```

```

output: pair of answer(x%lcm of modulo) and lcm of ↵
all the modulo (returns -1 if it is inconsistent)↵
*/
11 GCD(11 a, 11 b) { return (b == 0) ? a : GCD(b, a %↵
b); }
inline 11 LCM(11 a, 11 b) { return a / GCD(a, b) * b;↵
}
inline 11 normalize(11 x, 11 mod) { x %= mod; if (x <↵
0) x += mod; return x; }
struct GCD_type { 11 x, y, d; };
GCD_type ex_GCD(11 a, 11 b)
{
    if (b == 0) return {1, 0, a};
    GCD_type pom = ex_GCD(b, a % b);
    return {pom.y, pom.x - a / b * pom.y, pom.d};
}
pair<11,11> CRT(vector<11> &rem,vector<11> &mods)
{
    11 n=rem.size();
    11 ans=rem[0];
    11 lcm=mods[0];
    for(11 i=1;i<n;i++)
    {
        auto pom=ex_GCD(lcm,mods[i]);
        11 x1=pom.x;
        11 d=pom.d;
        if((rem[i]-ans)%d!=0) return {-1,0};
        ans=normalize(ans+x1*(rem[i]-ans)/d%(mods[i]/↵
d)*lcm,lcm*mods[i]/d);
        lcm=LCM(lcm,mods[i]); // you can save time by↵
replacing above lcm * n[i] /d by lcm = ↵
lcm * n[i] / d
    }
    return {ans,lcm};
}

```

## 6.2 Discrete Log

```

// Discrete Log , Baby-Step Giant-Step , e-maxx
// The idea is to make two functions,
// f1(p) , f2(q) and find p,q s.t.
// f1(p) = f2(q) by storing all possible values of f1↵
// and checking for q. In this case  $a^x \equiv b \pmod m$ ↵
// is
// solved by substituting x by p.n-q , where
// is choosen optimally , usually sqrt(m).
// returns a soln. for  $a^x \equiv b \pmod m$ 
// for given a,b,m . -1 if no. soln.
// complexity :  $O(\sqrt{m} \cdot \log(m))$ 
// use unordered_map to remove log factor.
// IMP : works only if a,m are co-prime. But can be ↵
modified.
int solve(int a, int b, int m) {
    int n = (int) sqrt (m + .0) + 1;
    int an = 1;

```

```

for (int i=0; i<n; ++i)
    an = (an * a) % m;
map<int,int> vals;
for (int i=1, cur=an; i<=n; ++i) {
    if (!vals.count(cur))
        vals[cur] = i;
    cur = (cur * an) % m;
}
for (int i=0, cur=b; i<=n; ++i) {
    if (vals.count(cur)) {
        int ans = vals[cur] * n - i;
        if (ans < m) return ans;
    }
    cur = (cur * a) % m;
}
return -1;
}

```

## 6.3 NTT

```

/*
Kevin's different Code: https://s3.amazonaws.com/codechef\_shared/download/Solutions/JUNE15/tester/MOREFB.cpp
****There is no problem that FFT can solve while this↵
NTT cannot
Case1: If the answer would be small choose a small ↵
enough NTT prime modulus
Case2: If the answer is large(> ~1e9) FFT would not↵
work anyway due to precision issues
In Case2 use NTT. If max_answer_size=n*(↵
largest_coefficient^2)
So use two or three modulus to solve it
****Compute  $a*b \pmod m$  if  $a \pmod m * b \pmod m$  would result in ↵
overflow in  $O(\log(a))$  time:
11 mulmod(11 a, 11 b, 11 mod) {
    11 res = 0;
    while (a != 0) {
        if (a & 1) res = (res + b) % m;
        a >>= 1;
        b = (b << 1) % m;
    }
    return res;
}
Fastest NTT (can also do polynomial multiplication if↵
max coefficients are upto  $1e18$  using 2 modulus ↵
and CRT)
How to use:
P=A*B
Polynomial1 =  $A[0] + A[1]*x^1 + A[2]*x^2 + \dots + A[n-1]*x^{n-1}$ 
Polynomial2 =  $B[0] + B[1]*x^1 + B[2]*x^2 + \dots + B[n-1]*x^{n-1}$ 
P=multiply(A,B)
A and B are not passed by reference because they are ↵
changed in multiply function
For CRT after obtaining answer modulo two primes p1 ↵
and p2:

```

```

}
reverse(a.begin() + 1, a.end());
fft(a);
a.resize(need);
return a;
}
vector<int> square(vector<int> a) {
    return multiply(a, a, 1);
}

```

## 6.4 Online FFT

    return -1;
}
```

## 7 Strings

### 7.1 Hashing Theory

If order not imp. and count/frequency imp. use this ←  
as hash fn:-

```
((a_1+h)^k + (a_2+h)^k + (a_3+h)^k + (a_4+h)^k ) % p ←
. Select : h,k,p
Alternate:
((x)^(a_1)+(x)^(a_2)+...+(x)^(a_k))%mod where x and ←
mod are fixed and a_1...a_k is an unordered set
```

### 7.2 Manacher

```
// Same idea as Z_algo, Time : O(n)
// [l,r] represents : boundaries of rightmost ←
// detected subpalindrom (with max r)
// takes string s and returns a vector of lengths of ←
// odd length palindrom
// centered around that char (e.g abac for 'b' returns ←
// 2(not 3))
vll manacher_odd(string s){
    ll n = s.length(); vll d1(n);
    for (ll i = 0, l = 0, r = -1; i<n; i++){
        d1[i] = 1;
        if (i <= r){
            d1[i] = min(r-i+1, d1[l+r-i]); // use prev ←
            val
        }
        while (i+d1[i] < n && i-d1[i] >= 0 && s[i+d1[i] ←
        ] == s[i-d1[i]]) d1[i]++; // trivial ←
        matching
        if (r < i+d1[i]-1) l=i-d1[i]+1, r=i+d1[i]-1; ←
        // update r
    }
    return d1;
}
// takes string s and returns vector of lengths of ←
// even length ...
// (it's centered around the right middle char, bb is ←
// centered around the later 'b')
vll manacher_even(string s){
    ll n = s.length(); vll d2(n);
    for (ll i = 0, l = 0, r = -1; i<n; i++){
        d2[i] = 0;
        if (i <= r){
            d2[i] = min(r-i+1, d2[l+r+1-i]);
        }
        while (i+d2[i] < n && i-d2[i]-1 >= 0 && s[i+d2 ←
        [i]] == s[i-d2[i]-1]) d2[i]++;
        if (d2[i] > 0 && r < i+d2[i]-1) l=i-d2[i], r=i ←
        +d2[i]-1;
    }
    return d2;
}
// Other mtd : To do both things in one pass, add ←
// special char e.g string "abc" => "$a$b$c$"
```

## 7.3 Trie

```
const ll AS = 26; // alphabet size
ll go[MAX][AS]; ll cnt[MAX]; ll cn=0;
// cn -> index of next new node
// convert all strings to vll
ll newNode() {
    for(ll i=0; i<AS; i++)
        go[cn][i]=-1;
    return cn++;
}
// call newNode once **** before adding anything **
void addTrie(vll &x) {
    ll v = 0;
    cnt[v]++;
    for(ll i=0; i<x.size(); i++){
        ll y=x[i];
        if(go[v][y]==-1)
            go[v][y]=newNode();
        v=go[v][y];
        cnt[v]++;
    }
}
// returns count of substrings with prefix x
ll getcount(vll &x){
    ll v=0;
    for(i=0; i<x.size(); i++){
        ll y=x[i];
        if(go[v][y]==-1)
            go[v][y]=newNode();
        v=go[v][y];
    }
    return cnt[v];
}
```

## 7.4 Z-algorithm

```
// [l,r] -> indices of the rightmost segment match
// (the detected segment that ends rightmost(with max ←
// r))
// 2 cases -> 1st. i ≤ r : z[i] is atleast min(r-i ←
// +1, z[i-1]), then match trivially
// 2nd. o.w compute z[i] with trivial matching
// update l,r
// Time : O(n)(asy. behavior), Proof : each iteration ←
// of inner while loop make r pointer advance to ←
// right,
// Applications: 1) Search substring(text t, ←
// pattern p) s = p + '$' + t.
// 3) String compression(s = t+t+...+t, then find |t ←
// |)
// 2) Number of distinct substrings (in O(n^2))
// (useful when appending or deleting characters ←
// online from the end or beginning)
```

```
vector<ll> z_function(string s) {
    ll n = (ll) s.length();
    vector<ll> z(n);
    for (ll i = 1, l = 0, r = 0; i < n; ++i) {
        if (i ≤ r)
            z[i] = min(r - i + 1, z[i - 1]); // use ←
            previous z val
        while (i + z[i] < n && s[z[i]] == s[i + z[i] ←
            ]) // trivial matching
            ++z[i];
        if (i + z[i] - 1 > r)
            l = i, r = i + z[i] - 1; // update ←
            rightmost segment matched
    }
    return z;
}
```

## 7.5 Aho Corasick

```
